Received 11 April 1996; accepted 10 October 1996

We have determined the nucleotide sequence of 129 524 bases of yeast (*Saccharomyces cerevisiae*) chromosome XV. Sequence analysis revealed the presence of 59 non-overlapping open reading frames (ORFs) of length >300 bp, three tRNA genes, four delta elements and one Ty-element. Among the 21 previously known yeast genes (36% of all ORFs in this fragment) were nucleoporin (NUP1), ras protein (RAS1), RNA polymerase III (RPC1) and elongation factor 2 (EF2). Further, 31 ORFs (53% of the total) were found to be homologous to known protein or DNA sequences, or sequence patterns. For seven ORFs (11% of the total) no homology was found. Among the most interesting protein identifications in this DNA fragment are an inositol polyphosphatase, the second gene of this type found in yeast (homologous to the human OCRL gene involved in Lowe's syndrome), a new ADP ribosylation factor of the arf6 subfamily, the first protein containing three C2 domains, and an ORF similar to a *Bacillus subtilis* cell-cycle related protein. For each ORF detailed sequence analysis was carried out, with a full consideration of its biological function and pointing out key regions of interest for further functional analysis. The sequence has been submitted to the EMBL data library under Accession Number X94335. © 1997 by John Wiley & Sons, Ltd.

#### INTRODUCTION

Chromosome XV with an estimated size of 1·108 megabases is the third largest chromosome of the budding yeast *Saccharomyces cerevisiae*. In the frame of the European Union yeast genome

project we have sequenced and analysed a cluster of nine overlapping cosmids covering the central region of the chromosome. The sequence of 129 524 bases has been submitted to the EMBL data library under accession number X94335. Here we discuss the structural features of this chromosomal region, base composition, density, distribution and orientation of genes. The detailed analysis carried out contributes to the current knowledge of the yeast genome in several aspects since it shows:

(i) sequences highly homologous to other yeast sequences, indicating genome duplication; (ii) new yeast sequences in already known protein families, suggesting new connections within the family and new perspectives for the function of the family; (iii) first occurrences in yeast of sequences in already known families, showing new biological or evolutionary aspects; (iv) new yeast sequences defining a new protein family and establishing cross-relations between species. Biological information is gathered by deciphering the conserved regions in protein families, and information about protein evolution is gained from phylogenetic interpretations.

## MATERIALS AND METHODS

### *Cosmids*

A cluster of nine ordered overlapping cosmids (pEOA347, pUOA522, pEOA246, pEOA273, pEOA306, pEOA265, pEOA106, pEOA986 and pEOA1081) covering the chromosomal region from 485 000 to 615 000 of chromosome XV was obtained in the EU project from the chromosome co-ordinator B. Dujon, Institut Pasteur, Paris. The cosmids were isolated and mapped as described by Thierry *et al.* (1995).

### *Subcloning strategy*

*Escherichia coli* strain XL1-Blue<sup>™</sup> (Stratagene) was used for all subcloning steps. In general, all *EcoRI* fragments of cosmid inserts were cloned into plasmid vector pUC18. One *EcoRI* fragment of about 1.7 kb (position 17 875–19 580) was not clonable into plasmids, therefore templates were prepared as biotinylated polymerase chain reaction (PCR) products for solid phase sequencing on magnetic beads (Hultman *et al.*, 1992) using neighbouring sequence information to design PCR primers. Another region from position 1140 to 6339 turned out to be unclonable in high copy number plasmids, but could be successfully cloned into low copy number plasmid pBR322.

### *DNA sequencing*

The entire sequence of 129 524 bp was determined on both strands mainly by directed primer walking strategy and T7 DNA polymerase with unlabelled primers and fluorescein-15\*dATP as internal label as described previously (Voss *et al.*, 1992). Sequences were analysed on two commercial ALF DNA sequencers (Pharmacia, Uppsala). After sequencing of plasmid subclones, linking of

adjacent *EcoRI* fragments was performed by direct cycle sequencing on cosmid DNA (Zimmermann *et al.*, 1994). Raw data collection and evaluation were performed using the ALF manager software; sequence assembly, data evaluation and presentation were performed with the EMBL GeneSkipper sequence analysis software (Schwager *et al.*, 1995).

### *Definition of open reading frames*

All open reading frames (ORFs) larger than 300 bp were translated using the standard genetic code, and independent database searches were carried out for each one. Names of the ORFs correspond to the general notation rule: YORnW stands for the Watson strand and YORnC for the Crick strand.

### *Data analysis*

The database searches for homologous sequences have been carried out using 'GENEQUIZ', a project management, browsing and visualization tool developed by the EMBL protein design group (Scharf *et al.*, 1994). The following databases were searched: protein sequence: PDB (Abola *et al.*, 1987), SwissProt (Bairoch and Apweiler, 1996), PIR-NBRF (fraction not overlapping with SwissProt; George *et al.*, 1996), GENPEPT (a direct translation of the DNA sequences in GenBank; Benson *et al.*, 1993), TREMBL (Bairoch and Apweiler, 1996); DNA sequence: EMBL (Rodriguez-Tome *et al.*, 1996), GenBank (Benson *et al.*, 1996), expressed sequence tags (ESTs) in dbEST (Boguski, 1995). Updated versions of the databases from 10 January 1996 were used. A continuous update of the results using the latest database versions is available through world wide web at <http://gredos.cnb.uam.es/yeast130.html>. Prior to the database scanning, sequences were masked using an algorithm to avoid spurious hits in regions of obvious composition bias (G. Casari *et al.*, unpublished).

The scan of the database was done using the BLAST (Altschul *et al.*, 1990) and FASTA (Pearson and Lipman, 1988) programs (parameters: BLOSUM62 matrix for BLAST; and Ktup=2 for FASTA). Multiple-sequence alignments were obtained using the programs MAXHOM (Sander and Schneider, 1991), CLUSTALW (Higgins *et al.*, 1992) or PILEUP (GCG package). Protein secondary structure was predicted from multiple sequence alignments using the PHD neural network method (Rost and Sander, 1994), as

implemented on the PredictProtein network server (Rost *et al.*, 1994). Phylogenetic trees based on the neighbour-joining method (Saitou and Nei, 1987) were calculated using the CLUSTALW package (Higgins *et al.*, 1992). Corrections for multiple replacements were applied (Kimura, 1983). The stability of trees with respect to different choices of subsets of residue positions was checked by bootstrapping experiments (Felsenstein, 1985). Profile searches were made using PROFILESEARCH (GCG) or MAXHOM (Sander and Schneider, 1991).

## RESULTS AND DISCUSSION

### DNA analysis

We report here sequencing and analysis of 129 524 bases of yeast (*S. cerevisiae*) chromosome XV (accession no. X94335). A schematic presentation of the distribution of 59 ORFs (plus one case of two overlapping ORFs of significant length), three tRNA genes, four delta elements, seven perfect ARS consensus sequences and one Ty-element is shown in Figure 1.

The average GC-content of the sequenced part is 38.5%, very similar to the GC-content of other known yeast chromosomes. A plot of the GC-content calculated over 10 kb windows every 100 bp shows two minima around positions 20 000 and 120 000 (data not shown). Whether this finding reflects any periodicity in GC-content over the whole chromosome as described for chromosomes II and XI (Feldmann *et al.*, 1994; Dujon *et al.*, 1994) will be confirmed when the complete chromosome sequence becomes available. Three of the four delta elements flank the Ty-element, two of the three tRNA genes are found in the proximity of delta elements, a phenomenon frequently observed in yeast.

Among the seven perfect ARS consensus sequences, the elements at positions 6679 and 6704 are the most probable active elements according to the observations from yeast chromosome VI (Murakami *et al.*, 1995). The density of coding regions in this chromosomal segment (one every 2.2 kb) is lower than that found on other known yeast chromosomes. On the other hand the average ORF size (550 codons) is larger than on all other chromosomes reported so far (457–503 codons), reflecting the fact that the sequence contains seven ORFs larger than 1000 codons. An unusual clustering on the Watson strand is observed over ten

ORFs within a stretch of 20 kb in the region from position 41 165 to 61 975.

In yeast, clustering of ORFs on one strand seems to occur in general more frequently than statistically expected, which raises the question whether it reflects polycistronic transcription, as recently observed in *Caenorhabditis elegans* (Spieth *et al.*, 1993) or whether it reflects a preferred arrangement to prevent collisions between the transcription and replication complexes (Brewer, 1988). Even more interestingly, the preferred number of ORFs in a cluster is in general five to seven; if a cluster contains more than five to seven ORFs on one strand, it is frequently interrupted in the middle by a delta element to form two units of clustered ORFs (chromosome I: position 180 000 to 194 000; chromosome III: position 154 000 to 174 000; chromosome VIII: position 81 000 to 99 000 and 451 000 to 473 000). Besides the ten uninterrupted ORFs found here in this fragment from chromosome XV, a comparable cluster has been found so far only in chromosome II in the region between position 345 000 and 375 000 (Feldmann *et al.*, 1994).

### Analysis of ORFs

The data analysis involved two steps: exhaustive search in databases and in-depth protein family analysis. In the first step, database scanning was performed using GENEQUIZ, a tool for the analysis of massive sequence data (Scharf *et al.*, 1994). GENEQUIZ uses daily updates of different databases, an integrated database search system, a rule-based engine for interpreting the results of homology searches, and an advanced human-machine interface (Casari *et al.*, 1995). The fraction of ORFs for which it was possible to assign a function in this fragment is relatively large (59%), larger than that for any other yeast chromosome. This is partly due to significantly improved searching strategies, as has been demonstrated in other cases (Casari *et al.*, 1995; Ouzounis *et al.*, 1996), but also due to the rapidly growing information in databases. The recent rapid increase in the number of database entries lacking primary functional annotation leads to an increasing number of cases where a sequence family emerges, yet no functional characterization is possible (corresponding to class (iv) described in the analysis below). A similarity search between the ORFs identified in this project and those in the public databases is summarized in Table 1.

Table 1. Position of the protein and DNA features found in the sequence reported.

The protein/DNA column indicates the closest homologue in the database. Unless stated otherwise, only SwissProt and TrEMBL protein sequence identifiers are used throughout the paper. SwissProt identifiers are presented with two words in capital letters joined by an underscore, the second referring to species. TrEMBL is a database of protein translation product from the EMBL DNA database. The TrEMBL identifiers are composed of the corresponding EMBL identifier followed by an underscore and a number that indicates the order of the translation product (since many consecutive translation products are frequently reported from the same EMBL entry). The EMBL accession number is given for DNA, one or two capital letters followed by a number. The score indicates the degree of homology, BLAST scores are listed when the closest homologue is a protein sequence, BLASTX scores in case of a nucleotide sequence (indicated by an 'n').

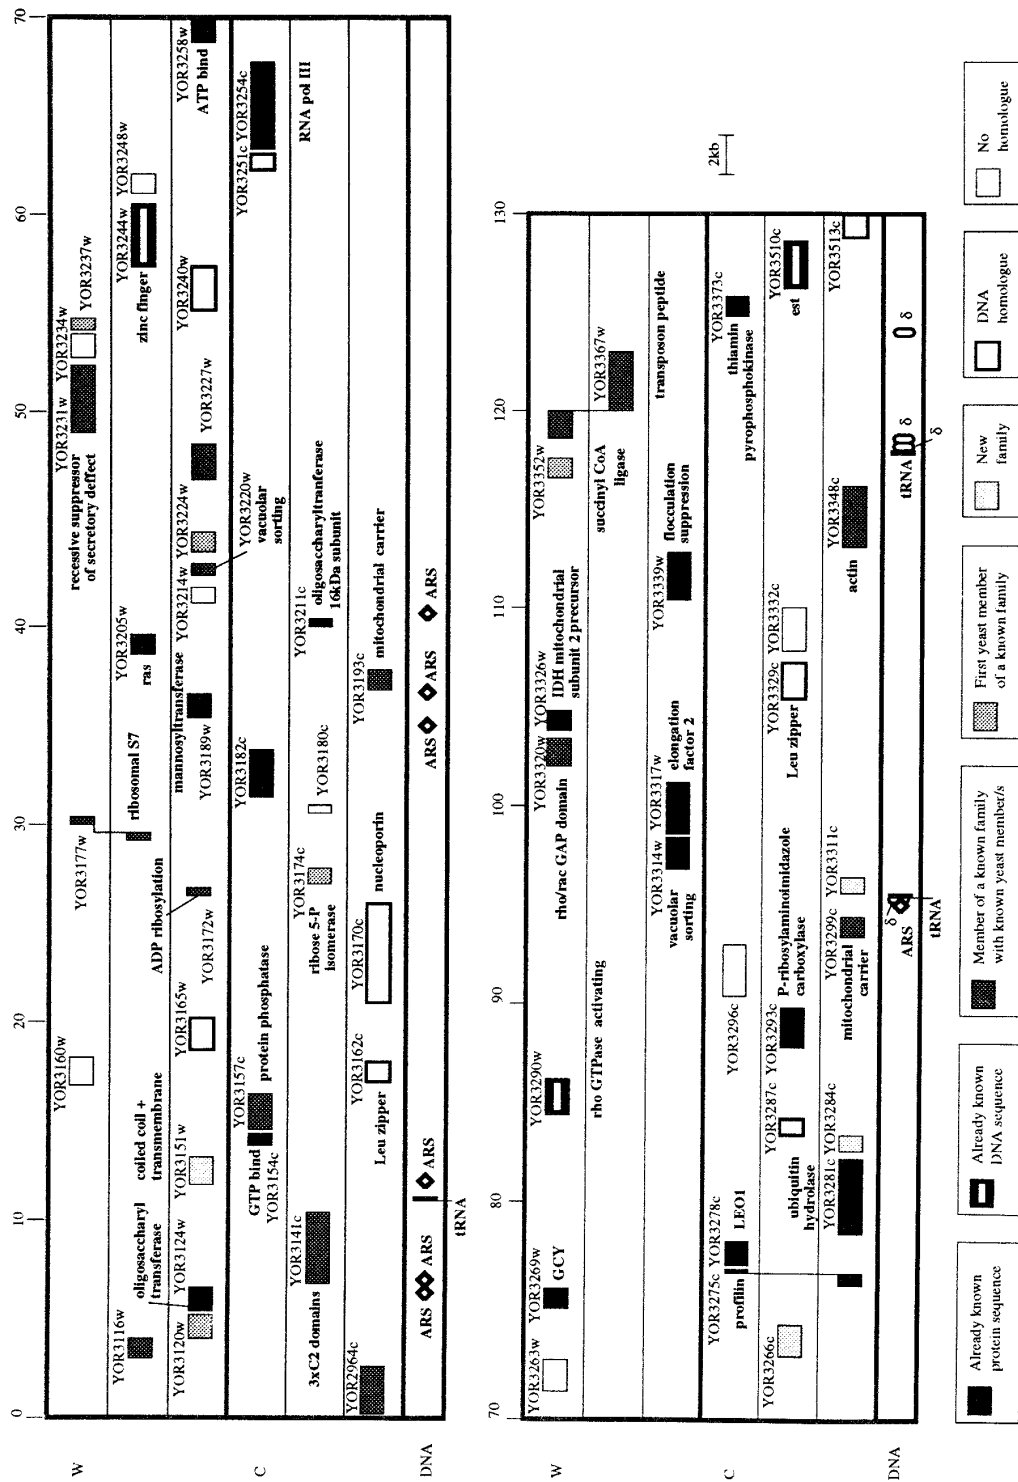

Figure 1. Protein and DNA features of accession no. X94335. Each box represents an ORF. Patterns and line thickness indicate the homology and functional characteristics of the corresponding ORF as stated in the legend below the figure. For each ORF the identifier and a short feature description (if known) are given. Note the striking accumulation of Watson ORFs from position 41 000 to 62 000.

Among the 59 ORFs identified here, 21 (36%) are identical to previously described genes, including nucleoporin (NUP1; Davis and Fink, 1990), ras protein (RAS1; Powers *et al.*, 1984), 16-kDa subunit of oligosaccharyl transferase (OST2; Silberstein *et al.*, 1995), RNA polymerase III (RPC1; Allison *et al.*, 1985) and elongation factor 2 (EF2; Perentesis *et al.*, 1992). The region from 74 600 to 82 000 has previously been found to contain the yeast genes *GCY* (Oechsner *et al.*, 1988), *PFY* (Magdolen *et al.*, 1988), *LEO1* (Magdolen *et al.*, 1994) and *UBP2* (Baker *et al.*, 1992). Thirty-one ORFs (53%) were found to be homologous to known protein or DNA sequence or patterns. For seven ORFs (11%) no homologous pattern was found. Eight small internal ORFs and eight small partially overlapping ORFs were excluded; these were in the size range from 100 to 150 codons and did not show any homology to database entries. However, we included the case of two overlapping ORFs (YOR3160w, 401 codons, ATG at position 16 789; YOR3162c, 326 codons, ATG at position 17 924) in our study. Both ORFs have significant length, the shorter ORF, YOR3162c, shows high homology to an *Arabidopsis thaliana* EST including a leucine zipper motif. In the case of the YOR3170c, a human EST was found 100% identical to the yeast sequence.

Two ORFs, YOR3177w and YOR3275c (identical to *PFY*), were predicted as intron-containing genes. Coding sequence for transposon peptide (YOR3367w) displays a +1 frameshift as is common for this type of sequence (Farabaugh, 1995). Among the most interesting protein identifications in this DNA fragment are (a) YOR3231w, an inositol polyphosphatase, the second found in yeast (homologous to the human OCRL gene involved in Lowe's syndrome); (b) YOR3172w, a new ADP ribosylation factor of the arf6 subfamily; (c) YOR3141c, the first protein containing three C2 domains; and (d) YOR3237w, an ORF similar to a *Bacillus subtilis* cell-cycle related protein.

#### Detailed analysis of selected ORFs

In the second step of the analysis, a detailed study of similarities between the different ORFs and sequences in databases was performed. In contrast to the high efficiency of the first step of database screening, the step of detailed analysis is not yet optimized and requires expert human intervention. Different cases, such as the ones described under (i) to (v), require a variety of

sophisticated strategies. Analysed ORFs were divided into: (i) sequences highly homologous to other yeast sequences indicating duplication in the genome; (ii) sequences belonging to already known protein families; (iii) first reported yeast sequences in already known families; (iv) yeast sequences facilitating establishment of new protein families and (v) sequences without homologues.

(i) *Sequences highly homologous to other yeast sequences indicating genome duplication* Case 1: YOR3227w (46 551–48 365; 604 amino acids, aa) is a potential isoform of the yeast enzyme  $\alpha$ -isopropyl-malate synthase. YOR3227w shows significant homology to the previously described yeast gene *LEU4* (Beltzer *et al.*, 1988), located on chromosome XIV, which encodes enzyme  $\alpha$ -isopropyl-malate synthase. The *LEU4* gene has two alternative in-frame translation initiation sites, leading to two proteins with different lengths (619 and 589 aa). The larger form is imported into the mitochondria due to an 18-residue amphiphilic helix on its N-terminus whereas the other form remains in the cytoplasm. The existence of at least one other gene encoding isopropyl-malate synthase in yeast has been reported (Chang *et al.*, 1985). Figure 2 shows an alignment of YOR3227w to the *LEU1\_YEAST* sequence. The assumption that YOR3227w corresponds to the isoform of the yeast  $\alpha$ -isopropyl-malate synthase is further supported by the following two observations: there is a methionine at a position where the alternative translation initiation starts in the *LEU4* gene, and the presence and organization of many directed and inverted repeats in the 5'-flanking region of the YOR3227w are similar to those in the same region of the *LEU4* gene (data not shown).

Case 2: YOR3177w (29 317–29 460+29 862–30 290; 190 aa) and YOR3165w (18 651–20 492; 613 aa) show homology to two adjacent ORFs on chromosome XIV. Dot-plot comparison between a 5.5 kb segment from chromosome XIV (accession no. X85811; Garcia-Cantalejo *et al.*, 1994) containing *Sctrnaorf\_1* and *Sctrnaorf\_2*, and the area between 17 500 and 31 000 from accession no. X94335 identified two homologous stretches around the region of YOR3177w and YOR3165w (data not shown). Although the ORFs *Sctrnaorf\_1* and *Sctrnaorf\_2* on chromosome XIV are adjacent to each other, the homologues on chromosome XV are interrupted by three ORFs over a distance of about 10 kb. The coding sequence of YOR3165w is homologous to *Sctrnaorf\_2*. YOR3177w is

Figure 2. Case 1. Alignment of the sequence YOR3227w with LEU1\_YEAST. (Note: there is an annotation conflict; the translation product of the *LEU4* gene is annotated as LEU1\_YEAST in SwissProt.) The homology between the two sequences is around 80%. The position of the second Met (labelled with #) is a possible second initiation site conserved in both sequences. The sequence of LEU1\_YEAST is longer (619 aa).

highly homologous to Sctrnaorf\_1 as shown in the multiple alignment (Figure 3). The sequences belong to the S7, 40S ribosomal subunit protein family. Both yeast sequences are interrupted by an intron of 401 bp (YOR3177w) or 345 bp (Sctrnaorf\_1), and have two exons of identical sizes of 48 and 142 aa, which indicates duplication in the yeast genome.

Case 3: ORFs YOR3193c (37 801–36 818; 327 aa) and YOR3299c (94 328–93 450; 292 aa) are similar to the yeast mitochondrial carrier protein YMC1. YOR3193c and YOR3299c belong to the diverged family of mitochondrial carrier proteins of several different substances (e.g. inorganic phosphate transporters, dicarboxylate exchangers etc.), which so far contains nine yeast proteins. The sequences of YOR3193c and YOR3299c display remarkable similarity to YMC1\_YEAST (located on chromosome XVI; Graf *et al.*, 1993). All three ORFs form a new sub-family and point to a more recent duplication within the YMC1 branch. From

the bootstrapping values it is possible to speculate that duplication of YOR3193c and YOR3299c might have occurred after the duplication which led to the YMC1 sequence. The presence of a delta element in the proximity of YOR3299c points to a possible involvement of transposition in this duplication process.

Case 4: YOR3116w (3059–3946; 295 aa) and YOR2964c (2714–465; 749 aa). Adjacent ORFs YOR3116w and YOR2964c are homologous to hypothetical yeast proteins YK71\_YEAST (152 aa) and YK69\_YEAST (910 aa), which are also adjacent on chromosome XI (Bou *et al.*, 1993; Garcia-Cantalejo *et al.*, 1994). BLAST scores are  $2.7\text{e-}247$  for YOR2964c/YK69\_YEAST and  $1.4\text{e-}4$  for YOR3116w/YK71\_YEAST. The orientation of the ORFs is maintained on both chromosomes. Since YOR3116w and YOR2964c are the first ORFs of the chromosomal fragment sequenced here, we cannot exclude that the region of duplication is extended beyond this point.

Figure 5. Case 7. The conservation levels in the arf family are mapped in the three-dimensional structure of the human ADP-ribosylation factor 1 complexed with GDP. The backbone is coloured in orange for those residues conserved in the whole arf family. White colour and side chains indicate residues conserved in the family except in YOR3172w. The substrate, GDP, and the  $Mg^{2+}$  ion are shown in ballmodel.

family. Figure 5 shows conservation levels in the arf family displayed in the three-dimensional structure of the human ARF1\_HUMAN complexed with GDP (Amor *et al.*, 1994). For more detailed protein sequence analysis of the arf6 family, see Valencia and Sander (1995). Non-conserved residues in YOR3172w involve the GDP binding site (Asp-Cys exchange in position 159, Lys-Pro exchange in position 131), the opposite face of the active centre (Val-Ala exchange in position 119, Val-Tyr exchange in position 167) and residues shown to interact with  $Mg^{2+}$  ions (Ser-Thr exchange in position 45).

Case 8: YOR3141c (10 305–6745; 1186 aa) contains three C2 domains. C2 domains, probably involved in  $Ca^{2+}$  and phospholipid binding, have been described in different protein families such as  $Ca^{2+}$ -dependent protein kinases C (Clark *et al.*, 1991); synaptotagmines, which are related to syn-

aptic vesicle traffic control (Sossin and Schwartz, 1993), and in *C. elegans* phorbol ester/DAG binding protein unc-13 (Bork and Sudol, 1994). Usually one or two C2 domains are present in these proteins. Analysis of YOR3141c revealed for the first time the presence of three C2 domains (termed YOR3141c1, c2 and c3) in a protein. Figure 6a shows a multiple alignment of the C2 domains from this ORF with their counterparts from other proteins (RSP5\_YEAST, KPC2\_HUMAN, SYT1\_RAT, PIPA\_DICDI, UN13\_CAEEL and PIR:A42142). The beta sheets derived from the published three-dimensional structure of the first C2 domain of SYT1\_RAT (Sutton *et al.*, 1995) are shown with boxes. The proteins did not align for the first beta sheet of the structure calculated. This first beta sheet is not even present in the case of RSP5\_YEAST. Thus only the last seven are shown (denoted as  $\beta 2$ – $\beta 8$ ). The phylogenetic analysis of

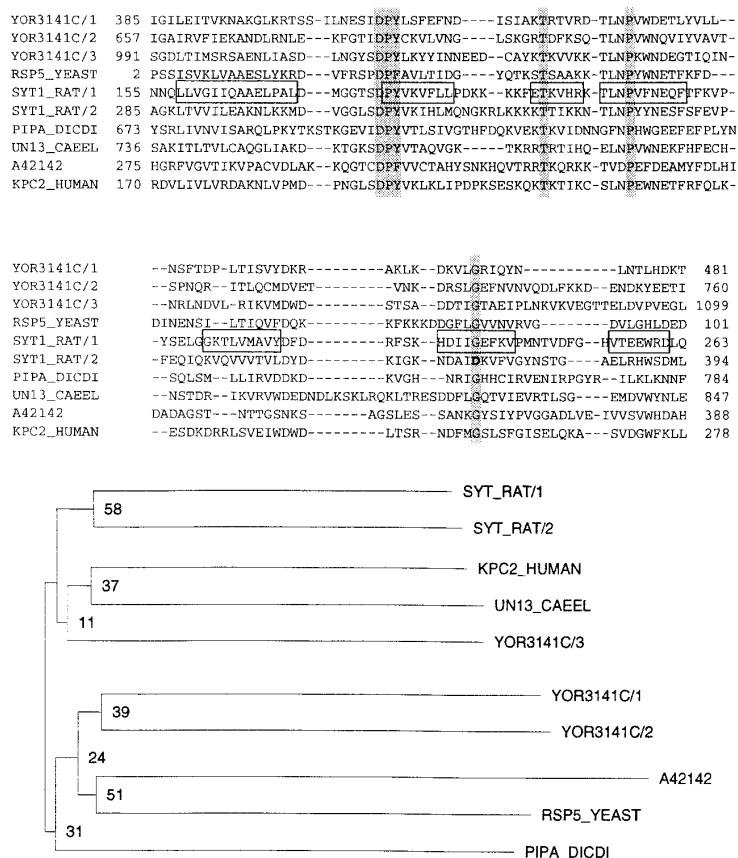

Figure 6. (a) Case 8. Alignment of the three C2 domains from YOR3141c with the C2 domains of other representative proteins. The alignment extends around 120 aa. The proteins are indicated by their SwissProt identifiers: KPC2\_HUMAN, protein kinase C; PIPA\_DICDI, phosphatidyl inositol phosphodiesterase; SYT1\_RAT, phospholipase c (their two C2 domains marked /1 or /2); A42142 (PIR database identifier), gap protein from *Drosophila*; RSP5\_YEAST, translation product from yeast; UN13\_CAEL, phorbol ester/DAG binding protein. YOR3141c/1, 2 and 3 are the C2 domains deduced from YOR3141c. Note that the only yeast sequences are the RSP5\_YEAST and the new ORF. The beta sheets as derived from the three-dimensional structure of the first C2 domain of rat synaptotagmin (Sutton *et al.*, 1995) are shown with open rectangles. The most conserved residues are shown in grey boxes. The importance of the 'G' in the centre of  $\beta 7$  is pointed out by the fact that it is mutated into a 'D' in the second C2 domain of synaptotagmin that is not functional. (b) Case 8. Tree of the previous alignment of C2 domains. The low bootstrapping values indicate the high divergence of the domain.

the C2 domains is shown in Figure 6b. YOR3141c domains 1 and 2 are closely related to each other while domain 3 is more related to synaptotagmin C2 domains (SYT\_RAT1, 2).

(iii) *First yeast sequences in already known protein families* In several cases ORFs deduced from the accession no. X94335 could be identified as the

first yeast member in an existing known protein family. These new findings could have interesting consequences for further biological and phylogenetic characterization of the protein families involved.

Case 9: YOR3352w (116 577–117 566; 329 aa) belongs to a family of CoA-ligases. YOR3352w is the first yeast member belonging to the family of

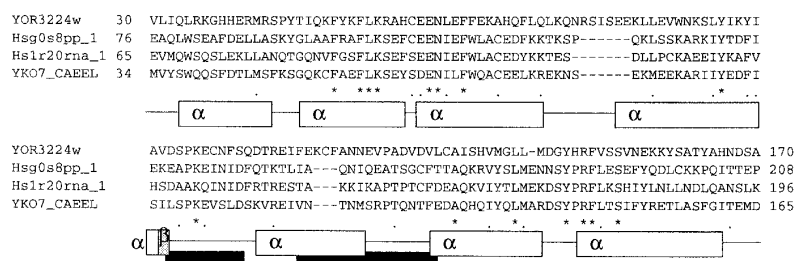

Figure 7. Case 10. YOR3224w is similar to two ORFs from human Hsg0s8pp\_1 (Hong *et al.*, 1993) and Hs1r20rna\_1 (Siderovski *et al.*, 1994), and to one ORF from *C. elegans* (YKO7\_CAEEL). Multiple sequence alignment with secondary structure prediction using PHD (Rost, 1994). Completely conserved residues are indicated by a (\*), highly conserved residues are marked by a (.). The two helices previously predicted for Hs1r20rna\_1 by Siderovski *et al.* are shown as black boxes.

CoA-ligases with known members from animals, plants and bacteria. It shows very high homology (identity approx. 60%) over the whole sequence.

Case 10: YOR3224w (44 876–45 805; 309 aa) is the fourth member in a family of proteins containing a previously incorrectly assigned helix-loop-helix (HLH) motif. YOR3224w is similar to human ORFs Hsg0s8pp\_1 (Hong *et al.*, 1993) and Hs1r20rna\_1 (Siderovski *et al.*, 1994) and to a *C. elegans* ORF YKO7\_CAEEL. In this case we propose a new protein family whose members are homologous and share common features in their secondary structure prediction. A previous comparison between the human ORF Hs1r20rna\_1 and HLH proteins (e.g. transcription factors) was based on a weak homology and on secondary structure prediction. The analysis presented here, obtained from alignment with mutually highly homologous sequences, allows a more precise definition of the family based on a more accurate secondary structure prediction deduced from general properties of the family rather than from individual sequences. The previous assignment of Hs1r20rna\_1 to HLH proteins was based on a similarity in two regions, the QTK and EAXKE motifs. However, Figure 7 (alignment obtained for four homologous sequences) clearly shows that these motifs are not conserved within the family. Furthermore, Siderovski *et al.* (1994) have suggested the similarity of the ORF Hs1r20rna\_1 with HLH proteins based on a secondary structure prediction of an HLH motif achieved by the Chou-Fasman method (Gribskov and Devereux, 1991). A new prediction performed for the newly established family indeed indicates the presence of two alpha helices for all members, but at different positions than in the classical HLH motif.

Case 11: YOR3120w (4113–5276; 387 aa) shares conserved motifs with prokaryotic members of the lipase-esterases family. ORF YOR3120w matches the PROSITE motif for lipases for the serine active site (PS00120) and represents the first eukaryotic sequence found with this motif. YOR3120w matches with a subset of the whole lipase-esterases family. The alignment shown in Figure 8 indicates an extension of the consensus sequence around the PROSITE pattern.

(iv) *Definition of a new protein family facilitated by the new sequence* With the progress of the genome sequencing projects, protein sequences without known function accumulate in the databases. Definition of new families where only sequences are available, but no biological information, can give important hints for the search for protein functions.

Case 12: YOR3237w (53 950–54 648; 232 aa) is the first eukaryotic member of a protein family presumably related to prokaryotic cell cycle proteins. Figure 9 shows that YOR3237w is similar to three proteins from *B. subtilis* and *E. coli*. However, only little functional information is available for the *B. subtilis* ORF MAF\_BACSU, which is coded by the *spoIIB* gene. This gene is flanked by many cell-cycle-related genes on the bacterial chromosome. It has been shown experimentally that MAF\_BACSU is involved in the cell cycle and particularly in septum formation: mutations in the *spoIIB* gene do not usually lead to a significant alteration of the spore formation, but if mutations in this gene are combined with inactivation of another sporulation gene (*spoVG*), the joint effect of the defective genes is an interruption of sporulation at the stage of septum formation (Margolis

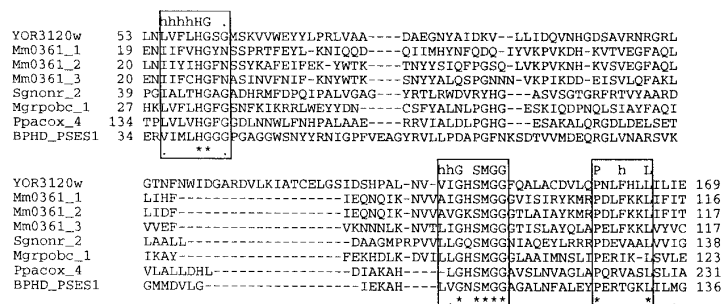

Figure 8. Case 11. YOR3120w. Alignment against products of the lipase-esterase operon from Mycoplasma (Mm0361\_1, Mm0361\_2 and Mm0361\_3), Sgnonr\_2 (antibiotic-resistance protein, 279 aa, *Streptomyces griseus*), Mgrpobc\_1 (unknown product, Mycoplasma), Ppaco\_4 (dihydrolipoamide acetyltransferase, Pseudomonas) and BHPD\_PSES1 (2-hydroxy-6-oxo-6-phenylhexa-2,4-dienoate hydrolase, Pseudomonas). The three conserved boxes are marked: hhhhHGx[G/N], hhGxSMGG, and PxxhxxL (h is a hydrophobic amino acid).

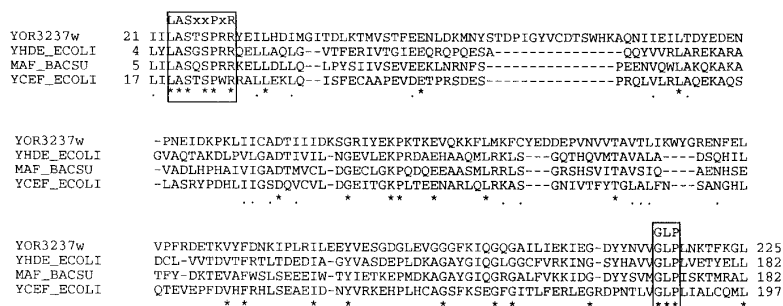

Figure 9. Case 12. YOR3237w is similar to *B. subtilis* and *E. coli* proteins with possible roles in the cell cycle. Multiple sequence alignment with main motifs boxed. Asterisks indicate residues conserved throughout the whole family; dots mark similar residues.

*et al.*, 1993). This finding suggests, though indirectly, the possible involvement of YOR3237w in the yeast cell cycle. Alignment of MAF\_BACSU with the deduced protein sequence of YOR3237w revealed the presence of two conserved regions at the N- and C-termini. Searches with the conserved sequence patterns LASxSPxR and GLP expanded the alignment by YHDE\_ECOLI and YCFE\_ECOLI, which are hypothetical proteins without known function. We propose the inclusion of these two sequences as additional representatives of this new family.

Case 13: YOR3174c (27 851–27 075; 258 aa) is the first homologue of *E. coli* ribose-5P isomerase (RPIA\_ECOLI). Figure 10 shows a sequence alignment of YOR3174c to RPIA\_ECOLI. The presence of the second sequence allows us to pin-point conserved residues which may facilitate determination of the active site. From the 71

Figure 10. Case 13. Full sequence alignment of YOR3174c to RPIA\_ECOLI. Highly conserved motifs are boxed, conserved residues are marked by an (\*), similar residues are indicated as a (.)

residues conserved between these two sequences the best candidates for active site functions are four clusters with characteristic patterns of Gly

Figure 12. Case 15. Alignment of ORF YOR3513c against several ESTs (see text for details). Asterisks indicate positions where all the fragments show identical residues. No gaps were allowed for the alignment.

residues: GxGxGST, DGADE, QxIKGGGA and GxxDG (boxed).

Case 14: YOR3510c (128 612–126 237; 791 aa). Figure 11 shows that YOR3510c can be aligned to a small set of DNA binding proteins coding for transcription and replication factors. The alignment allows the definition of profiles like LxGxxx-hGKxTxxxhxxEh or aVDxhxxxxDRG, where x is any amino acid, h is a hydrophobic residue, and a denotes an acid residue.

Case 15: YOR3513c (129 523–128 867; 175 aa). It is very likely that YOR3513c is expressed since its EST (T39061) is already known. Figure 12 shows that YOR3513c is highly homologous in the N-terminus to human D22835 and rice T10779 ESTs and in the C-terminal region to rice D28195, yeast T38107, R03754 (*C. briggsae*) and human T40124 ESTs.

(v) *No homologue* We identified ORFs without clear homology to any database entry, but still likely to code for protein since they are in compliance with the following criteria: they are long enough to be coding, do not overlap with other ORFs with assigned function, and have an aa

composition and GC content typical for coding regions in yeast. YOR3170c (25 975–21 029; 1648 aa) has no significant hit against the protein databases but it shows an almost 100% identity with a human EST dbest-gln-4055. Other large ORFs without clear homologues are YOR3296c (893 aa) and YOR3329c (622 aa). An overview of ORFs larger than 100 aa and non-overlapping ORFs with clear homologues is shown in Table 1 and Figure 1.

Since the yeast genome sequence is now complete and several bacterial genome sequences are available, linking large-scale DNA sequencing with database searches and detailed case-to-case analysis is increasingly profitable. Data analysis of the type discussed here is an increasingly important bridge between the accumulation of raw sequence data and the planning of functional analysis experiments aiming at detailed elucidation of gene function.

## ACKNOWLEDGEMENTS

DNA sequencing was supported by the European Union yeast genome sequencing programme. The support of the GENEQUIZ consortium and especially of Georg Casari are gratefully acknowledged. The protein design group of CNB-CSIC is financed by grant BIO94-1067 from CICYT, Spain.
